District Wheels Dispatch Directory

Repeat orders should not mean digging through old chats.

Meta messages can be slow and laggy. I search the name taped to the car, then copy the saved details into the courier booking site.

Who uses it

I use it when a repeat buyer orders a car for shipping.

01 **Read the buyer name on the tape on the car**

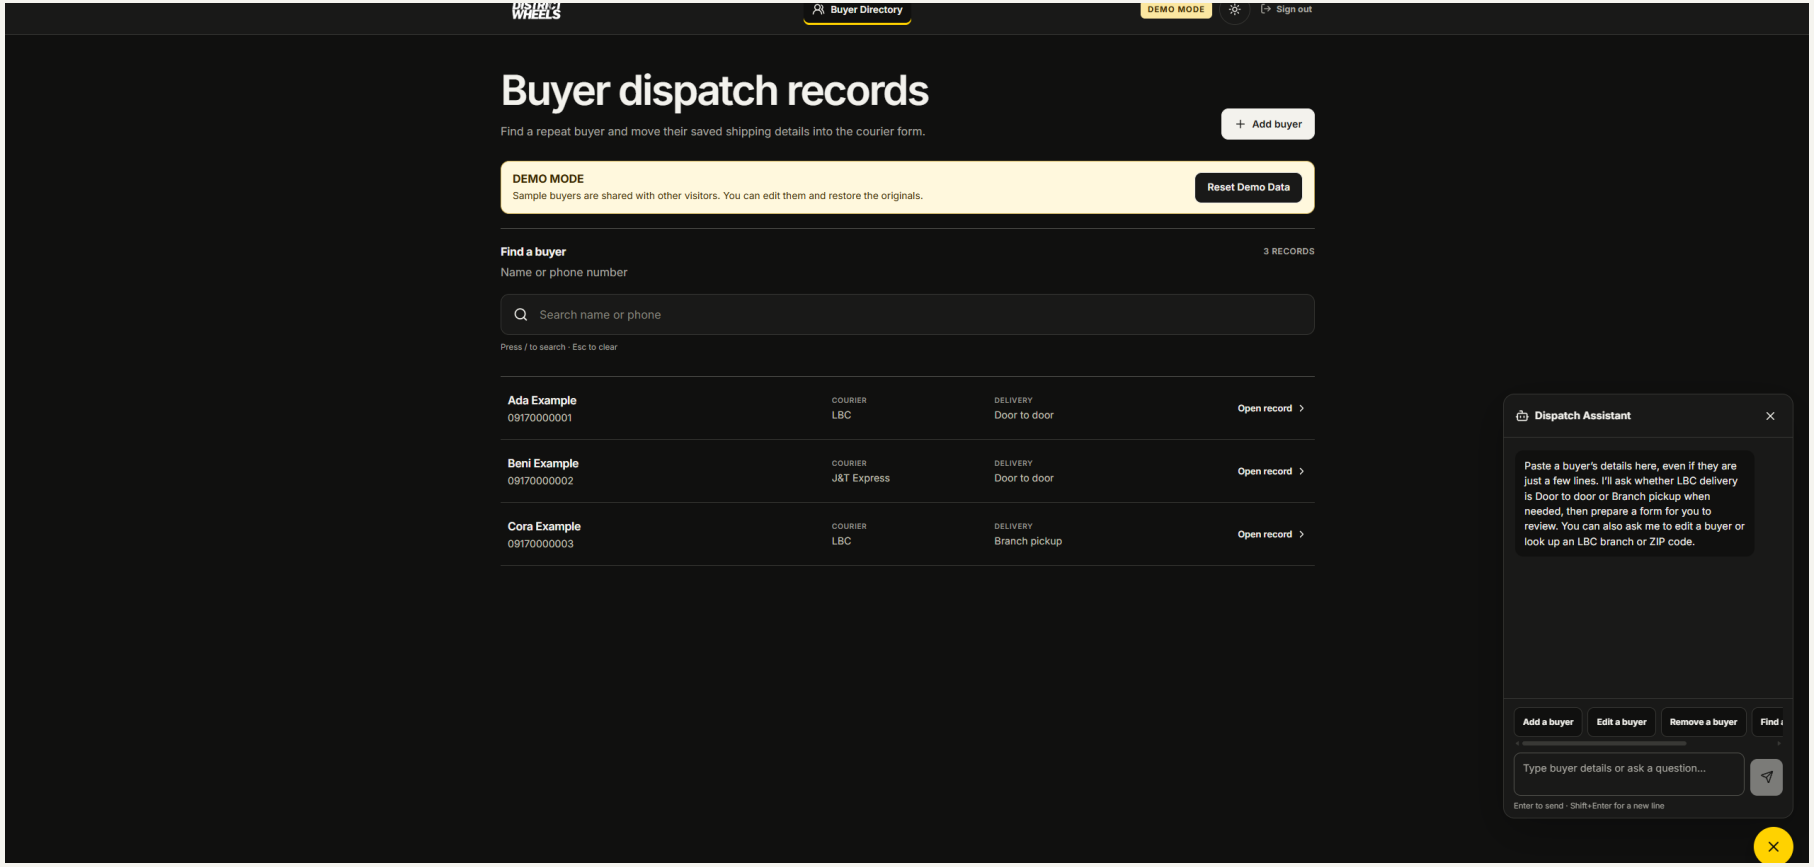

02 Search that name and open the saved record

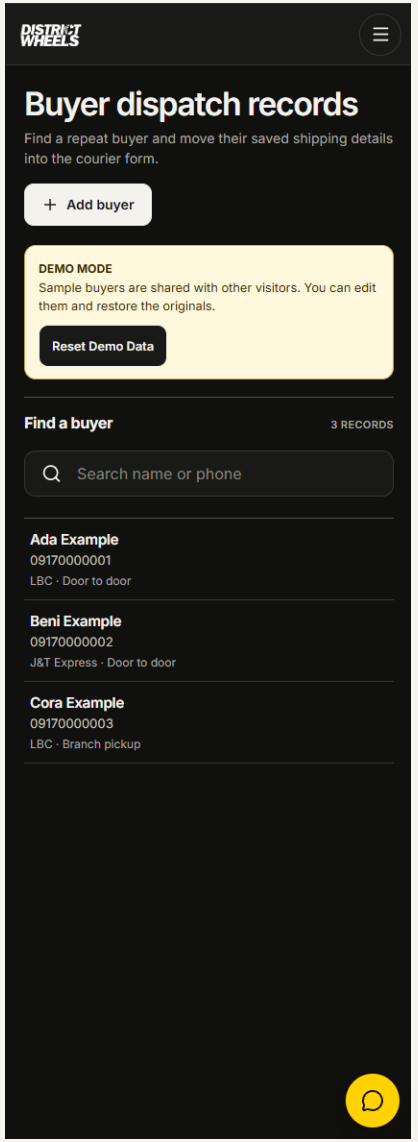

03 Check and copy the shipping details

04 Paste them into the courier booking website

App demo

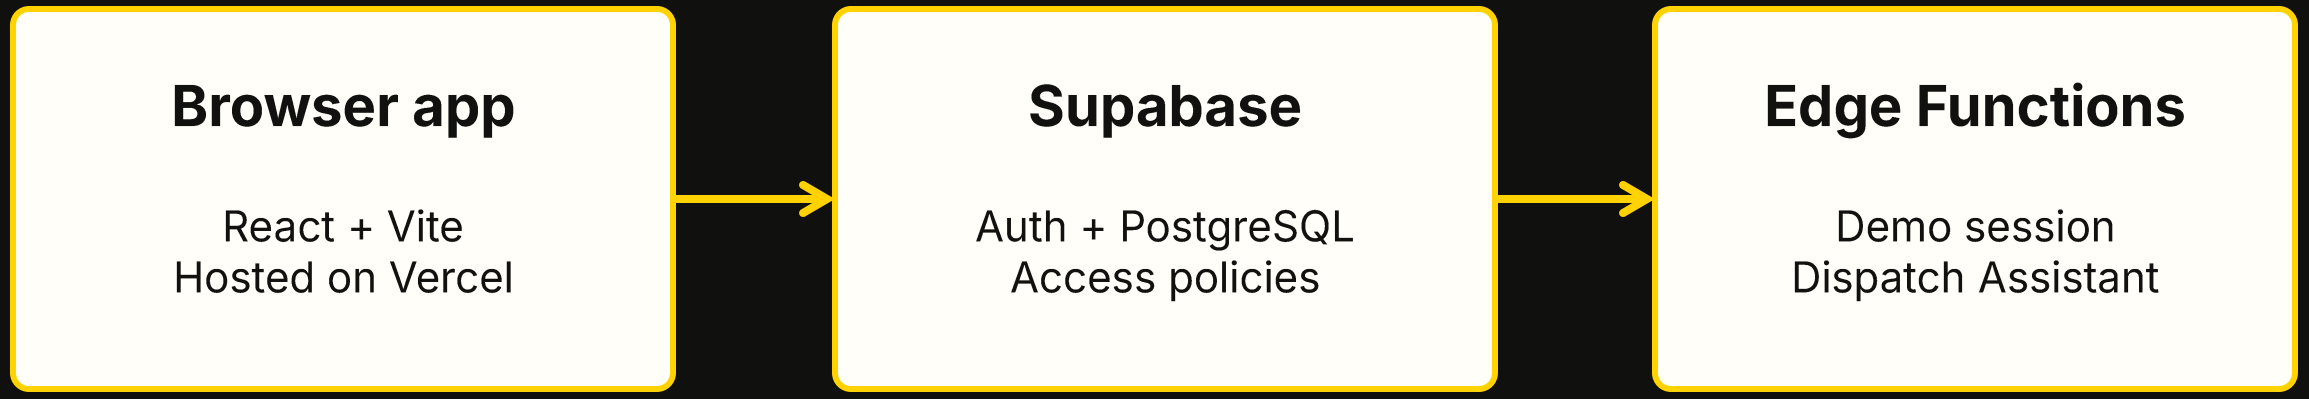

Fictional records in the deployed demo

How the app works

The deployed browser uses Supabase directly.

A separate Express API remains for local development and tests.

Challenges I worked through

01 Phone numbers came in different formats

I wrote the early storage and copy normalization, then tested formatted and plain numbers.

02 The assistant chose branch pickup for a door address

I reported the failing example and required the delivery choice to stay explicit. Codex changed the parser and added a test.

I built the first website and directed and tested much of the later Codex-built work.

What I would improve next

01 Make fresh Supabase setup and demo seeding repeatable.

02 Automate checks for deployed sign-in, demo, and assistant flows.

03 Decide whether to retire the separate Express API or secure it for public use.
